Abstract. Elliptic curve cryptosystems (ECC) are new generations of public key cryptosystems that have a smaller key size for the same level of security. The exponentiation on elliptic curve is the most important operation in ECC, so when the ECC is put into practice, the major problem is how to enhance the speed of the exponentiation. It is thus of great interest to develop algorithms for exponentiation, which allow efficient implementations of ECC.

In this paper, we improve efficient algorithm for exponentiation on elliptic curves defined over $\mathbf{F}_p$ in terms of affine coordinates. The algorithm computes $2^{n_2}(2^{n_1}P+Q)$ directly from random points P and Q on an elliptic curve, without computing the intermediate points. Moreover, we apply the algorithm to exponentiation on elliptic curves with width-w Mutual Opposite Form (wMOF) and analyze their computational complexity. This algorithm can speed up the wMOF exponentiation of elliptic curves of size 160-bit about (21.7 %) as a result of its implementation with respect to affine coordinates.

1 Introduction

Elliptic curve cryptosystems, which were suggested independently by Miller[7] and Koblitz[5], are new generation of public key cryptosystems that have smaller key sizes for the same level of security.

The elliptic curve cryptographic operations, like encryption/decryption schemes generation/verification signature, require computing of exponentiation on elliptic curve. The computational performance of elliptic curve cryptographic protocol such as Diffie-Hellman [3] Key Exchange protocol strongly depends on the efficiency of exponentiation, because it is the costliest operation. Therefore, it is very attractive to speed up exponentiation by providing algorithms that allow efficient implementations of elliptic curve cryptosystems [1][4][6][8][9][12].

There are typical methods for exponentiation such as binary methods and windowing methods[9]. These methods can speed up exponentiation by reducing additions, where addition of two points and doubling of two points are performed repeatedly.

One of the efficient windowing methods is *w*MOF[11]. It is a base-2 representation which provide the minimal hamming weight of exponent. Its great advantage is that it can be generated from left-to-right which means, that the recoding doesn't have to be done in a separate stage, but can be performed on-the-fly during the evaluation. As a result, it is no longer necessary to store the whole recoded exponent, but only small parts at once.

Another approach to speed up exponentiation is by increasing the speed of doublings. One method to speed the doublings is direct computation of several doubling, which computes 2^nP directly from P $\in$ E($\mathbf{F}_q$), without computing intermediate points 2P,2^2P,…,2^{n-1}. Sakai and Sakurai[12] proposed formulae for computing 2^nP directly ($\forall n \geq 1$) on E($\mathbf{F}_p$) in terms of affine coordinates. Since modular inversion is more expensive than multiplication, their formulae requires only one inversion for computing 2^nP instead of n inversions in usual add-double method.

In this paper, we improve efficient algorithm for exponentiation on elliptic curve defined over $\mathbf{F}_p$ in terms of affine coordinates. We construct efficient formulae to compute $2^{n_2}(2^{n_1}P+Q)$ directly from P, Q $\in$ E($\mathbf{F}_p$), without computing intermediate points $2P,2^2P,\cdots,2^{n_1}P$, $2(2^{n_1}P+Q),\cdots,2^{n_2-1}(2^{n_1}P+Q)$, where $n_1 \geq 1$. Our formulae have computational complexity (4n+10)M + (4n+6)S +

I **,** where M, S and I denote multiplication, squaring and inversion respectively in $\mathbf{F}_p$, and $n=n_1 + n_2$.

Moreover, we show in which way this new algorithm for direct computing $2^{n_2}(2^{n_1}P+Q)$ can be combined with wMOF exponentiation method [11]. We also implement wMOF exponentiation with and without these formulae and discuss the efficiency. The result of this implementation shows that 21.7% speed increase in wMOF exponentiation with these formulae on elliptic curve of size 160-bit.

Let $\mathbf{F}_p$ denotes a prime finite field with p elements.

We consider an elliptic curve E given by Weierstrass non-homogeneous equation:

$$E: y^2 = x^3 + ax + b$$

where $a, b \in \mathbf{F}_p$, $p > 3$, and $4a^3 + 27b^2 \neq 0$(i.e. E is smooth).

Let $P_1 = (x_1, y_1)$, $P_1' = (x_1', y_1')$, $P_{2^n} = 2^n P_1 = (x_{2^n}, y_{2^n}) \in E(\mathbf{F}_p)$.

Let the elliptic curve point addition and doubling be denoted by ECADD and ECDBL, respectively. Let M, S and I denote multiplication, squaring and inversion, respectively in $\mathbf{F}_p$, where S = 0.8M, as it is customary nowadays.

This paper is organized as follows: In Sect. 1, we give some definitions and notations. In Sect. 2, we summarize pervious work. In Sect. 3, we will describe our algorithm for direct computing of $2^{n_2}(2^{n_1}P+Q)$ in terms of affine coordinates. In Sect. 4, we use this algorithm in exponentiation with wMOF method, and show in what way these new derived formulae can improve the speed of the exponentiation. In Sect. 5 timing of our implementation will be given. Finally conclusions will be given in Sect. 6.

2 Previous work

In this section, we summarize the known algorithms for point addition, point doublings, and direct doublings.

2.1 Point addition

In terms of affine coordinates, point addition can be computed as follows:

Let $P_1 = (x_1, y_1)$, and $Q = (x, y), \neq O$ where O denotes the point at infinity, then $P' = (x', y')$ can be computed as follows

$$x' = \lambda^2 - x_1 - x$$

$$y' = \lambda (x_1 - x') - y_1$$

$$\lambda = \frac{(y - y_1)}{(x - x_1)} \qquad (2.1)$$

The formulae above have computational complexity S + 2M + I. [2]

2.2 Point doubling

In terms of affine coordinates, point addition can be computed as follows: Assume Let $P_1 = (x_1, y_1) \neq O$ where O denotes the point at infinity, then $2P = P_2 = (x_2, y_2)$ can be computed as follows

$$x_2 = \lambda^2 - 2x_1$$

$$y_2 = \lambda (x_1 - x_2) - y_1$$

$$\lambda = \frac{3x_1^2 + a}{2y_1} \qquad (2.2)$$

The formulae above have computational complexity 2S + 2M + I [2]

2.3 Direct Doubling

One method to increase the speed of doublings is direct computation of several doublings, which can compute 2^nP directly from $P \in E(\mathbf{F}_q)$, without computing the intermediate points $2P, 2^2P, \ldots, 2^{n-1}$[12].

Guajardo and Paar[4] suggested increase doubling speed by formulating algorithms for direct computation of 4P, 8P, and 16P on elliptic curves over $\mathbf{F}_{2^m}$ in terms of affine coordinates.

Sakai and Sakurai[12] proposed formulae for computing 2^nP directly ($\forall n \geq 1$) on $E(\mathbf{F}_p)$ in terms of affine coordinates. These formulae require only one inversion for computing 2^nP instead of n inversions in regular add-double method.

In affine coordinate, direct computation requires only one inversion for computing 2^nP instead of n inversions in regular add-double method. Therefore direct computation of several doublings may be effective in elliptic curve

exponentiation in terms of affine coordinate, since modular inversion is more expensive than modular multiplication [12]

3 Direct Computation of $2^{n_2}(2^{n_1}P+Q)$ in affine coordinate

In this section, we derive formulae for computing $2^{n_2}(2^{n_1}P+Q)$ directly from a given point P, Q $\in$ E($\mathbf{F}_p$) without computing the intermediate points $2P, 2^2P, \cdots, 2^{n_1}P$, $2(2^{n_1}P+Q), \cdots, 2^{n_2-1}(2^{n_1}P+Q)$, where $n_1 \geq 1$, in terms of affine coordinate. These formulae can work with *w*MOF exponentiation method[11].

We begin by constructing formulae for small n_1, n_2, then we will construct algorithm for general n_1, n_2.

As an example**,** let $n_1 = 2$, $n_2 = 1$, let $P_1 = (x_1, y_1)$, Q = (x, y), $P_1' = (x_1', y_1') \in$ E($\mathbf{F}_p$) then for an elliptic curve with Weierstrass form in terms of affine coordinates $P_2' = 2P_1' = 2(4P_1+Q) = (x_2', y_2')$ can computed as the following:

1) Computing $4P_1$ as in [12]

$4P_1 = P_4 = (x_4, y_4)$ can be computed as follows.

Let

$$C_0 = y_1$$

$$A_0 = x_1$$

$$B_0 = 3x_1^2 + a$$

$$A_1 = B_0^2 - 8A_0C_0^2$$

$$C_1 = -8C_0^4 - B_0(A_1 - 4A_0C_0^2)$$

$$B_1 = 3A_1^2 + 16aC_0^4$$

$$A_2 = B_1^2 - 8A_1C_1^2$$

$$C_2 = -8C_1^4 - B_1(A_2 - 4A_1C_1^2)$$

Then $4P_1 = P_4 = (x_4, y_4)$ can be computed as follows.

$$x_4 = \frac{A_2}{(4C_0C_1)^2} \tag{3.1}$$

$$y_4 = \frac{C_2}{(4C_0C_1)^3} \tag{3.2}$$

2) Computing $(4P_1+Q)$

Assume $4P_1 = (x_4, y_4) \neq -Q$, recall from Sect. 2.1, the point addition then $P_1' = (x_1', y_1') = (4P_1+Q)$ in term of affine coordinates, can be computed as follows:

$$\lambda = \frac{C_2 - (4C_0C_1)^3 y}{(4C_0C_1)(A_2 - (4C_0C_1)^2 x)} \tag{3.3}$$

Now let

$T = C_2 - (4C_0C_1)^3 y$, $S = A_2 - (4C_0C_1)^2 x$, we get:

$$\lambda = \frac{T}{(4C_0C_1)S} \tag{3.4}$$

Substituting λ, and x_4 into the expression for x_1', we find

$$x_1' = \frac{T^2 - S^2(A_2 + (4C_0C_1)^2 x}{(4C_0C_1)^2 S^2} \tag{3.5}$$

Let $M = A_2 + (4C_0C_1)^2 x$, we get :

$$x_1' = \frac{T^2 - MS^2}{(4C_0C_1)^2 S^2} \tag{3.6}$$

Let $A_0' = T^2 - MS^2$ and, substituting λ, and x_1' into the expression for y_1', we get:

$$y_1' = \frac{-(4C_0C_1)^3 yS^3 - T(A_0' - (4C_0C_1)^2 xS^2)}{(4C_0C_1)^3 S^3} \tag{3.7}$$

Let $C_0' = -(4C_0C_1)^3 yS^3 - T(A_0' - (4C_0C_1)^2 xS^2)$, we get:

$$y_1' = \frac{C_0'}{(4C_0C_1)^3 S^3} \tag{3.8}$$

3) Computing $2(4P_1+Q) = 2P_1'$

Recall from Sect. 2.2, the point doubling, then $2P'_1 = P'_2 = (x'_2, y'_2)$ in term of affine coordinates, can be computed as follows:

$$\lambda = \frac{3A'^2_0 + a(4C_0C_1)^4S^4}{2C'_0(4C_0C_1)S} \tag{3.9}$$

Now, let $B'_0 = 3A'^2_0 + a(4C_0C_1)^4S^4$ and, substituting λ, and x'_1 into the expression for x'_2, we find:

$$x'_2 = \frac{B'^2_0 - 8A'_0C'^2_0}{(2C'_0)^2(4C_0C_1)^2S^2} \tag{3.10}$$

Let $A'_1 = B'^2_0 - 8A'_0C'^2_0$, and substituting λ, y'_1, x'_1 and x'_2 into the expression for y'_2, we find

$$y'_2 = \frac{-8C'^4_0 - B'_0(A'_1 - 4A'_0C'^2_0)}{(2C'_0)^3(4C_0C_1)^3S^3} \tag{3.11}$$

Let $C'_1 = -8C'^4_0 - B'_0(A'_1 - 4A'_0C'^2_0)$, we get finally:

$$y'_2 = \frac{C'_1}{(2C'_0)^3(4C_0C_1)^3S^3} \tag{3.12}$$

The formulae above have computational complexity 18S + 22M + I

3.1 The formulae Computing $2^{n_2}(2^{n_1}P + Q)$ in Affine Coordinate

From the above formulae for direct computing $2(4P_1 + Q)$, we can easily obtain general formulae that allow direct computing $2^{n_2}(2^{n_1}P + Q)$ for $n_1 \geq 1$. Algorithm 3.1 describes these formulae.

Algorithm 3.1 Direct Computation of $2^{n_2}(2^{n_1}P + Q)$ in affine coordinate, where $n_1 \geq 1$, and P, Q $\in$ E($\mathbf{F}_p$) .

INPUT: $P_1 = (x_1, y_1)$, $Q = (x, y) \in E(\mathbf{F}_p)$

OUTPUT: $P'_{2^{n_2}} = 2^{n_2}P' = 2^{n_2}(2^{n_1}P_1 + Q) = (x'_{2^{n_2}}, y'_{2^{n_2}}) \in E(\mathbf{F}_p)$

1. Compute A_0 and C_0 and B_0

$C_0 = y_1$

$A_0 = x_1$

$B_0 = 3x_1^2 + a$

2. For i from 1 to n_1 Compute A_i, C_i, for i from 1 to $n_1 - 1$ Compute B_i

$A_i = B_{i-1}^2 - 8A_{i-1}C_{i-1}^2$

$C_i = -8C_{i-1}^4 - B_{i-1}(A_i - 4A_{i-1}C_{i-1}^2)$

$B_i = 3A_i^2 + 16^i a(\prod_{j=0}^{i-1} C_j)^4$

3. Compute the N, V, W, Z then A'_0, C'_0

$N = A_{n_1} - (2^{n_1} \prod_{i=0}^{n_1-1} C_i)^2 x$

$V = A_{n_1} + (2^{n_1} \prod_{i=0}^{n_1-1} C_i)^2 x$

$W = C_{n_1} - (2^{n_1} \prod_{i=0}^{n_1-1} C_i)^3 y$

$Z = (2^{k_1} \prod_{i=0}^{k_1-1} C_i) N$

$A'_0 = W^2 - VN^2$

$C'_0 = -Z^3 y - W(A'_0 - Z^2 x)$

4. *if* $(n_2 > 0)$

Compute B'_0

$B'_0 = 3A'^2_0 + aZ^4$

For i from 1 to n_2 Compute A'_i, C'_i , for i from 1 to $n_2 - 1$ Compute B'_i

$A'_i = B'^2_{i-1} - 8A'_i C'^2_i$

$C'_i = -8C'^4_{i-1} - B'_{i-1}(A'_i - 4A'_i C'^2_i)$

$$B'_i = 3A'^2_{i-1} + 16^i aZ^4 (\prod_{j=0}^{i-1} C'_j)^4$$

Compute Z

$$Z = Z(2^{n_2} \prod_{i=0}^{n_2-1} C'_i)$$

5. Compute $x'_{2^{k_2}}, y'_{2^{k_2}}$

$$x'_{2^{n_2}} = \frac{A'_{n_2}}{Z^2}$$

$$y'_{2^{n_2}} = \frac{C'_{n_2}}{Z^3}$$

Theorem 3.1 describes the computational complexity of this formula.

Theorem 3.*1* *In terms of affine coordinates, there exits an algorithm that computes* $2^{n_2}(2^{n_1}P+Q)$ *at most [4(n+2) +2] M, [4(n+1) + 2]S , and I in* $\mathbf{F}_p$ *for any point* $P,Q \in E(\mathbf{F}_p)$ *where M, S and I denote multiplication, squaring and inversion respectively, and* $n = n_1 + n_2$.

The proof is given in Appendix A.

3.2 Complexity Comparison

For application in practice it is highly relevant to compare the complexity of our algorithm for direct computing of $2^{n_2}(2^{n_1}P+Q)$ with regular add-double method which requires (n_1+n_2) separated doublings and one addition, and with Sakai-Sakuri algorithm[12] for computing $2^{n_1+n_2}P$ and $2^{n_2}Q$. The performance of the new method depends on the cost factor of one inversion relatively to the cost of one multiplication. For this purpose, we introduce, as [4], the notation of a "break even point." It is possible to express the time that it takes to perform one inversion in terms of the equivalent number of multiplication needed per inversion.

In general let $n = n_1 + n_2$, let us denote the direct computing of $2^{n_2}(2^{n_1}P + Q)$ by symbol DECDBL(n). Then our formulae can outperform the regular double and add algorithm if the following relation to hold:

Cost(separate n ECDBL + ECADD) > Cost(DECDBL(n))

Calculation $2^{n_2}(2^{n_1}P + Q)$ where	Method	Complexity			Break-Even Point
		S	*M*	*I*	
$n_1+n_2 = 3$	DECDBL(*3*)	18	22	1	$7.6\,M < I$
	3 doublings + 1 addition	8	7	4	
$n_1+n_2 = 4$	DECDBL(*4*)	22	26	1	$6.6\,M < I$
	4 doublings + 1 addition	10	9	5	
$n_1+n_2 = 5$	DECDBL(*5*)	26	30	1	$6\,M < I$
	5 doublings + 1 addition	12	11	6	
$n_1+n_2 = n$	DECDBL(*n*)	4*n*+6	4*n*+10	1	$\frac{(3.6\,n+12)}{n} M < I$
	n doublings + 1 addition	2*n*+1	2*n*+2	*n*+1	

Table 3.1 Complexity comparison: direct computing of $2^{n_2}(2^{n_1}P + Q)$ vs. Individual (n_1+n_2) doublings and one addition.

Calculation $2^{n_2}(2^{n_1}P + Q)$ where	Method	Complexity			Break-Even Point
		S	*M*	*I*	
$n_1 = 4$, $n_2=0$	DECDBL(*4*)	22	26	1	$4.2\,M < I$
	Sakai-Sakuri algorithm	19	20	3	
$n_1 = 3$, $n_2=1$	DECDBL(*4*)	22	26	1	$0.6\,M < I$
	Sakai-Sakuri algorithm	23	24	3	
$n_1 = 2$, $n_2=2$	DECDBL(*4*)	22	26	1	$-3\,M < I$
	Sakai-Sakuri algorithm	27	28	3	
$n_1 + n_2=n$	DECDBL(*4*)	4*n*+6	4*n*+10	1	$\frac{8.4 - 7.2n_2}{2} M < I$
	Sakai-Sakuri algorithm	$4(n+n_2)+3$	$4(n+n_2+1)$	3	

Table 3.2 Complexity comparison: direct computing of $2^{n_2}(2^{n_1}P+Q)$ vs. direct computing of $2^{n_1+n_2}P$ and $2^{n_2}Q$.

Ignoring squarings and additions and expressing the Cost function in terms of multiplications and inversions, we have:

$$(2n\,M + 2n\,S + n\,I + 2M + S + I) > (4(n+2)M + 4(n+1)S + 2M + 2S + I)$$

We define r = *I/M* (the ratio of speed between a multiplication and inversion), and assume that one squaring has complexity $S = 0.8\,M$[12]. We also assume that the cost of field addition and multiplication by small constants can be ignored. One can rewrite the above expressions as:

$$n\,r\,M > (2nM + 8M + 1.6n\,M + 4M)$$

Solving for r in terms of *M* one obtains:

$$r > \frac{(3.6\,n + 12)}{n}$$

As we see from Table 3.1, if a field inversion has complexity I > 7.6 *M*, direct computation of 3 doublings and one addition may be more efficient than 3 separate doubling and one addition.

Moreover, our algorithm for direct computing of $2^{n_2}(2^{n_1}P+Q)$ can outperform Sakai-Sakuri algorithm for computing $2^{n_1+n_2}P$ and $2^{n_2}Q$ if:

Cost(direct computing of $2^{n_1+n_2}P$ and direct computing of $2^{n_2}Q$ and then simply adding the two) > Cost(DECDBL(n_1+n_2))

In case, we ignore squarings and additions and expressing the Cost function in terms of multiplications and inversions, we have:

$$[(4n+1)\,M + (4n+1)S + (4n_2+1)\,M + (4n_2+1)S + 3I + 2M + S\ ] > [\,4(n+2)M + 4(n+1)S + 2M + 2S + I]$$

After simplification we can rewrite the above expressions as:

$$2I > 6M + 3S - 4n_2S - 4n_2M$$

Solving for r in terms of *M* one obtains:

$$r > \frac{8.4 - 7.2n_2}{2}$$

As we see from Table 3.2, if a field inversion has complexity I > 4.2 *M*, direct computation of *4* doublings and one addition by using our algorithm is more efficient than *4* doublings by using Sakai-Sakuri algorithm and then performing one addition. Also, it clear from the table and the above discussion that DECDBL(*n*) is different from the Sakai-Sakuri algorithm for computing $2^{n_1+n_2}P$ and $2^{n_2}Q$. $2^{n_2}(2^{n_1}P+Q)$.

3.2 Exponentiation with Direct Computation of $2^{n_2}(2^{n_1}P+Q)$

By using our previous formulae for direct computation of $2^{n_2}(2^{n_1}P+Q)$, where $n_1 \geq 1$, and P,Q $\in$ E($\mathbf{F}_p$), we can improve algorithm B.1 [11] for elliptic curve exponentiation with *w*MOF by change the step 3.2 of algorithm B.1 [11] with a new step that compute $2^{n_2}(2^{n_1}P+Q)$ directly as in the following algorithm.

Algorithm 3.2 Exponentiation with wMOF Using Direct Computation of $2^{n_2}(2^{n_1}P+Q)$

INPUT a non-zero t-bit binary string k, P$\in$ E($\mathbf{F}_p$), and the multiple of the point P, $\gamma_{0...tw}$ and $\xi_{0...tw}$, the precomputed table look-up .

OUTPUT exponentiation kP.

1. i $\leftarrow$ t
2. Q $\leftarrow$ *O*
3. While i $\geq$ 1 do the following
   - 3.1. if (k_i XOR k_{i-1}) = 0, then do the following
     - 3.1.1. Q $\leftarrow$ECDBL(Q)
     - 3.1.2. i $\leftarrow$ i - 1
   - 3.2. else do the following
     - 3.2.1. index $\leftarrow$ ((k >> (i - *w*)) & (2^{w+1} - 1)) - 2^{w-1}
     - 3.2.2. if (i < *w*) Q $\leftarrow$ $2^{\,i-(w-\xi_{index})+1}$ ($2^{w-\xi_{index}}$ Q + γ_{index}P)
     - 3.2.3 else if (i $\geq$ *w*) Q $\leftarrow$ $2^{\xi_{index}}$ ($2^{\,w-\xi_{index}}$ Q + γ_{index}P)
     - 3.2.4. i $\leftarrow$ i - *w*
4. If i = 0 do the following

4.1. Q ← ECDBL(Q)

4.2. If $k_0 = 1$ then Q ← ECADD(Q,-P)

5. return Q

In algorithm 3.2, for each window width *w* of *w*MOF, Step 3.1 performs direct computation of $2^{i-(w-\xi index)+1}(2^{w-\xi index} Q + \gamma_{index}P)$ if ($i < w$) otherwise Step 3.2 performs direct computations of $2^{\xi index}(2^{w-\xi index} Q + \gamma_{index}P)$ if ($i \geq w$), where $\xi_{index} = 0,1,\ldots w\text{-}1$, $\gamma_{index}P = \{\pm 1, \pm 3, ..., \pm(2^{w-1} - 1)\}$.

3.3 Complexity Analysis of the wMOF Method

In this subsection, we perform an analysis of *w*MOF method when it used in conjunction with the $2^{n_2}(2^{n_1}P + Q)$ formulae. In addition, we compare the complexity of *w*MOF method, with and without formulae. Moreover we derive an expression that predicts the theoretical improvement of the *w*MOF method by using the formulae, in terms of the ratio between inversion and multiplication times.

Theorem 3.2 describes the complexity of algorithm B.1 [11] for computing exponentiation with *w*MOF.

Theorem 3.2 *In terms of affine coordinate, let* $P \in E(\mathbf{F}_p)$**,** *t-digits exponent in w*MOF*, then the complexity of algorithm* B.1 [11] *for computing kP requires on average* $\frac{(2w+4)t}{w+1}M + \frac{(2w+3)t}{w+1}S + \frac{(w+2)t}{w+1}I$ *,where M, S and I denote multiplication, squaring and inversion respectively.*

The proof is given in Appendix A.

Now Theorem 3.3 describes the complexity of algorithm 3.1 for computing exponentiation with wMOF by using $2^{n_2}(2^{n_1}P + Q)$.

Theorem 3.3 *In terms of affine coordinate,* **let** $P \in E(\mathbf{F}_p)$**,** *and t-digits exponent in w*MOF*, then the complexity of algorithm 3.1 for computing kP requires on*

average $\frac{4(w+3)t}{w+1}M + \frac{4(w+2)t}{w+1}S + \frac{2t}{w+1}I$ *, where M, S and I denote multiplication, squaring and inversion respectively.*

The proof is given in Appendix A.

Relative Improvement

Let us denote the times it would take to perform exponentiation by using algorithms B.1[11], and 3.1 by symbols $T_{\text{Regular method}}$, $T_{\text{Formula method}}$ respectively. According to theorems B.1[11], and 3.1, we can derive expressions for the time it would take to perform a whole exponentiation with *w*MOF as:

$$T_{\text{Regular method}} = \frac{(2w+4)t}{w+1}M + \frac{(2w+3)t}{w+1}S + \frac{(w+2)t}{w+1}I \quad (3.21)$$

$$T_{\text{Formula method}} = \frac{4(w+3)t}{w+1}M + \frac{4(w+2)t}{w+1}S + \frac{2t}{w+1}I \quad (3.22)$$

From equations 3.21, and 3.22, one can readily derive the relative improvement by defining r = I/M (the ratio of speed between a multiplication and inversion) as:

$$\text{Relative Improvement} = \frac{T_{\text{Regular method}} - T_{\text{Formula method}}}{T_{\text{Regular method}}} \quad (3.23)$$

By using (3.21) and (3.22)

$$\text{Relative Improvement} = \frac{wI - [(2w+8)M + (2w+5)S]}{(w+2)I + [(2w+4)M + (2w+3)S]} \quad (3.24)$$

In our implementation S ≈ M and r = 12.6, let $w = 4$, then

$$\text{Relative Improvement is} = \frac{4(r) - 29}{6(r) + 23} \quad (3.25)$$

$$\text{Relative Improvement is} = \frac{4(12.6) - 29}{6(12.6) + 23} \cdot 100 = 21.7\ \% \quad (3.26)$$

4 Implementation and Results

In this section, we implement our methods and others, which have been given in previous sections to show the actual performance of exponentiation. Implementation of an ECC system has several choices. These include selection of elliptic curve domain parameters, platforms [1].

4.1 Elliptic Curves domain parameters and Platforms

Generating the domain parameters for elliptic curve is vary time consuming. It consists of a suitably chosen elliptic curve E defined over a prime finite field $\mathbf{F}_p$, and a base point $G \in E(\mathbf{F}_p)$. Therefore we select NIST-recommended elliptic curves domain parameters in [10]. We implement 4 elliptic curves over prime fields $\mathbf{F}_p$, the prime modulo p are of a special type (generalized Mersenne numbers) with $\log_2 p$ =160, 192, 224, 256. We call these curves as P160, P192, P224, or 256 respectively.

The ECC is implemented on a Pentium 4 personal computer (PC) with 2.0 GHz processor and 512 MB of RAM. Programs were written in Java language for multi-precision integer operations, and are ran under Windows XP.

4.2 Timings analysis of *w*MOF Exponentiation Method

We performed timing measurements on the individual k doublings and one addition operations and the corresponding formulae for direct computation of one addition adjoint with k doublings. In addition, we developed timing estimates based on the approximately ratio of speed between a multiplication and inversion I/ M in prime filed $\mathbf{F}_p$ as presented in Table 4.1.

Curves	Average Timing (μsec) for M	Average Timing (μsec) for S	Average Timing (μsec) for I	r = I / M
P160	7.0	6.9	88.0	12.6
P192	8.7	8.6	108.8	12.5
P224	10	9.8	123.1	12.3
P256	11.9	11.8	145.2	12.2

Table 4.1 The ratio of speed between a multiplication and inversion in prime filed $\mathbf{F}_p$

4.2.1 Optimal Window Size

To show the actual improvement of *w*MOF method with our new formula, we must find out the most efficiency proper window size, where the length of input binary form is 160-bits, 192-bits, 224-bits, or 256-bits. Figures (4.1- 4.4) illustrate the relation among the window size w, the speed of the evaluation and pre-

computed processes. We can notice from these Figures that when the window size increases, time of the evaluation will decrease, while time of the precomputation will increase, and the optimal *w* is 4 when the input is 160-bits, and the optimal *w* is 5 when the inputs is 192, 224 or 256-bits. So all the tests in this paper will be processed for *w* = 4 in 160-bits input and *w* = 5 for 192, 224, or 256-bits.

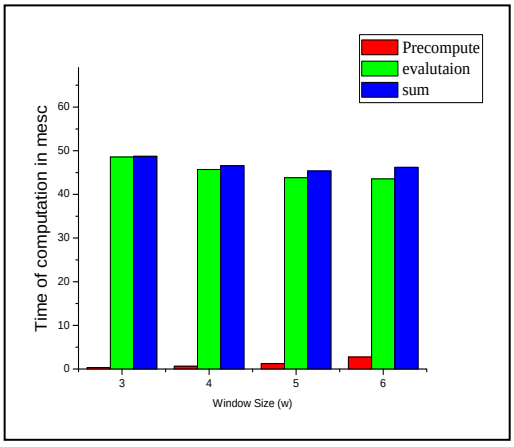

Figure 4.3 Pre-compute and evaluation with 224-bits input

4.2.2 The performance of improved *w*MOF method

Using Table 4.1, we can readily predict that the timings for performing a exponentiation with and without the formulae presented in Algorithm 3.1. In addition, using the complexity shown in equations (3.21, 3.22) and the timings shown in Table 4.1 we can make estimates as to how long an exponentiation with wMOF will take using both doublings with formulae and individual doublings.

Curves	Method	Predicted Timing	Measured Timing	% Improvement	
				Predicted	Measured
P 160	wMOF with formulae (w = 4)	17.4	18.3	21.62	21.8
	wMOF (w = 4)	22.2	23.4		
P 192	wMOF with formulae (w = 5)	23.8	24.3	25.62	25.7
	wMOF (w = 5)	32	32.6		
P 224	wMOF with formulae (w = 5)	31.7	33.9	24.52	24.6
	wMOF (w = 5)	42	45		
P 256	wMOF with formulae (w = 5)	43.8	47.4	23.5	23.3
	wMOF (w = 5)	57.3	61.8

5 Conclusion

In this paper, we constructed efficient algorithm for exponentiation on elliptic curve defined over $\mathbf{F}_p$ in terms of affine coordinates. The algorithm computes $2^{n_2}(2^{n_1}P+Q)$ directly from random points P and Q on an elliptic curve, without computing the intermediate points. We showed that our algorithm for computing $2^{n_2}(2^{n_1}P+Q)$ is more efficient than Sakai-Sakuri algorithm for computing $2^{n_1+n_2}P$ and $2^{n_2}Q$. A comparison was made based on notation of a "break even point," which is the cost factor of one inversion relatively to the cost of one multiplication. Moreover, we applied the algorithm to exponentiation on elliptic curve with wMOF and analyze its computational complexity.
This algorithm can speed the wMOF exponentiation of elliptic curve of size 160-bit about (21.7 %) as a result of its implementation with respect to affine coordinates.

Appendix A: Computational Complexity

In this Appendix, we give proof of theorems 3.1, 3.2, 3.3. In the following proofs, we ignore the cost of a field addition and a subtraction, as well as the cost a multiplication by small constants.

A.1 Theorem 3.1

Proof The complexity of step 1 and step 2 (the same as in [12, Algorithm1]) involve $(2M + 3S)n_1 + (M+S)(n_1 -1)$ + S

In step 3, we first compute $\prod_{i=0}^{n_1-1} C_i$ which takes n_1-1 multiplication. Secondly, we perform one squaring to compute $(2^{n_1}\prod_{i=0}^{n_1-1} C_i)^2$. Next, we perform one multiplication to compute $(2^{n_1}\prod_{i=0}^{n_1-1} C_i)^2 x$. Then we obtain N, and V. Next, we perform two multiplications, one multiplication to compute $(2^{n_1}\prod_{i=0}^{n_1-1} C_i)^2 y$ and other to compute $(2^{n_1}\prod_{i=0}^{n_1-1} C_i)(2^{n_1}\prod_{i=0}^{n_1-1} C_i)^2 y = (2^{n_1}\prod_{i=0}^{n_1-1} C_i)^3 y$. Then we obtain W. Third, we perform two squaring to compute W^2, N^2, and one multiplication to compute VN^2. Then we obtain A'_0. Fourth, we perform one multiplication to compute $(2^{n_1}\prod_{i=0}^{n_1-1} C_i)N$. Then we obtain Z. Next, we perform two squaring to

compute Z^2, Z^4, and one multiplication to compute Z^3. Next, we perform two multiplications to compute Z^2x, z^3y, Finally, we perform one multiplication to compute $W(A'_0 - Z^2x)$. Then we obtain C'_0. The complexity of step 3 involves $(n_1 -1)M + 9M + 5S$.

In step 4 we perform one squaring to compute A'^2_0. Next we perform one multiplication to compute aZ^4, where Z^4 is computed in step 3. Then we obtain B'_0. The complexity of step 4.1 involve M + S and the complexity of step 4.2 involves $(2M + 3S)n_2 + (M+S)(n_2 -1)$ as step 2.

In step 4.3 we compute $\prod_{i=0}^{n_2-1} C'_i$ which takes n_2-1 multiplications. Secondly, we perform one multiplication to compute $Z(2^{n_2} \prod_{i=0}^{n_2-1} C'_i)$. Then we obtain new value for Z. the complexity of 4.3 involves $n_2 M$. Hence, the complexity of step 4 involves $4n_2 M + 4n_2 S$.

In step 5, we perform one inversion to compute Z^{-1} and the result is set to T. Next, we perform one squaring to compute T^2. Next, we perform one multiplication to compute $A'_{n_2} T^2$. Then we obtain $x'_{2^{n_2}}$. Finally we perform two multiplications to compute $C'_{n_2} T^2 T$. Then we obtain $y'_{2^{n_2}}$. The complexity of step 5 involves $3M + S + I$. So the complexity of above computations involve $[4(n+2) +2] M, [4(n+1) + 2]S,$ where $n= n_1 + n_2$. □

A.2 Theorem 3.2

Proof We noticed that algorithm B.1 [11] performs an ECADD operation each time the current digit δ is non-zero, recall from theorem 4 [11] that the average non-zero density of *w*MOF is asymptotically $\frac{1}{w+1}$ also, one ECDBL operation is performed in each iteration (where i ≥ 0) to double the intermediate result. Then

on average, algorithm B.1 [11] for computing exponentiation with wMOF requires

$$t\,\text{ECDBL} + \frac{t}{w+1}\text{ECADD}$$

Recall that the computational costs for doubling and additions operations in affine coordinate. Then we can rewrite previous expression as:

$$(2M + 2S + I)t + \frac{t}{w+1}(2M + S + I)$$

We can rewrite previous expression in terms of M, S, and I as:

$$\frac{(2w+4)t}{w+1}M + \frac{(2w+3)t}{w+1}S + \frac{(w+2)t}{w+1}I$$ □

A.3 Theorem 3.3

Proof Recall from theorem 4 [11] that for t-digits exponent k in its *w*MOF, if $t \to \infty$ the average non-zero density of *w*MOF is asymptotically $\frac{1}{w+1}$ and *w*MOF of k is infinity.

Long sequence constituted from two types of blocks:

1. $b_1 = (0)$, length of this block is 1;
2. $b_2 = (0^i * 0^{w-i-1})$, length of this block is w and $0 \le i \le w - 1$;

Then the number of block b_2 equals $\frac{1}{w+1}$ because every block b_2 has a non-zero bit, and the number of block b_1 equals amount of 0s in *w*MOF – the amount of 0s in b_2 which equals

$$\frac{w}{w+1}t - (w-1)(\frac{1}{w+1})t = \frac{t}{w+1}$$

Now, step 3.1 of algorithm 3.1 performs $\frac{1}{w+1}t$ blocks b_1 and step 3.2 performs $\frac{1}{w+1}t$ block b_2 then algorithm 3.1 for computing *kP* requires on average

$$\frac{t}{w+1}\text{ECDBL} + \frac{t}{w+1}\text{DECDBL}(w)$$

Recall the computational costs for doublings and additions operations in affine coordinate. Then we can rewrite previous expression as:

$$\frac{n}{w+1}(2M+2S+I + 4(w+2)M + 4(w+1)S + 2M + 2S + I)$$

We can rewrite previous expression in terms of M, S, and I as:

$$\frac{4(w+3)t}{w+1}M + \frac{4(w+2)t}{w+1}S + \frac{2t}{w+1}I$$
